

A short written summary answering:

- What does each row in the dataset represent?
- What are the main business fields in the dataset?
- What are the total sales, total profit, and overall profit margin?
- What percentage of transactions are loss-making?
- Are there any missing values, duplicated rows, or unusual values?

Week 1 Summary

Each row in the dataset represents one product-level transaction within an order. If a customer buys multiple products in the same order, the order can appear in multiple rows. The main business fields for each row in the dataset are **Row ID, Order ID, Order Date, Segment, Region, Category, Sub-Category, Product ID, Product Name, Sales, Quantity, Discount, and Profit.**

After cleaning the data:

total sales : \$2,297,200.86

total profit : \$286,397.02

overall profit margin : 12.47%.

There are **1,871 loss-making transactions** out of 9,994 total transactions.

This means **18.72% of the transactions have negative profit.**

I did not find any missing values in the required analysis columns. I also did not find duplicated rows or duplicated Row ID values. Sales and Quantity values are all greater than 0, and Discount values are between 0 and 1.
